

On the herpetofauna of Lake Vrana and its vicinity (Dalmacia, Croatia) (Amphibia, Reptilia)

Zur Herpetofauna des Vrana Sees und seiner Umgebung (Dalmatien, Kroatien)
(Amphibia, Reptilia)

NUŠA VOGRIN

KURZFASSUNG

Bei herpetologischen Felderhebungen am Vrana See und in der benachbarten adriatischen Küstenregion (Dalmatien, Kroatien) wurde das Vorkommen von 13 Reptiliens- und zwei Amphibienarten festgestellt. Der Fundort Drage von *Lacerta oxycephala* liegt 30 km nördlich der bisher bekannten Arealgrenze der Art.

ABSTRACT

Thirteen reptilian and two amphibian species were observed at Lake Vrana and the adjacent Adriatic coastal area (Dalmacia, Croatia). *Lacerta oxycephala* was found in Drage, about 30 km north of the known range of the species.

KEY WORDS

Amphibia, Reptilia; herpetofauna of Lake Vrana, Dalmacia, Croatia; northernmost record of *Lacerta oxycephala*

Knowledge on the herpetofauna of the Adriatic coast in Croatia is basicly derived from investigations carried out in Kvarner, i. e. in mountainous areas (e. g., Mt. Velebit and Mt. Biokovo) or on islands (e. g., RADOVANOVIC 1951; BRELIH 1961; BRELIH & ĐŽUKIĆ 1974; MRSIĆ 1977; MRSIĆ & al. 1989; TVRTKOVIĆ & KLETČEKI 1993a, 1993b; TOME 1995). The herpetofauna of lowland areas is little known or even lacks any data.

Between August 12 and 20, 1996, herpetological field work was carried out at Lake Vrana and the adjacent Adriatic coastal area (Dalmacia, Croatia) (fig. 1). All types of habitats present were included in the study in which 'Systematic Sampling Survey' (SCOTT 1994) was applied during different times of the day. Some morphometric data of the animals caught were recorded (tables 1 to 2).

Lake Vrana covers 3000 ha being the largest natural lake in Croatia. Most parts of the lake shores are covered with *Phragmites australis*, most strikingly in the ornithological reserve (30 ha) on the northeasten shore. In the flooded areas next to the lake proper the dominant vegetation is *Juncus* sp. Many fields in the vicinity are

irrigated with water from the lake. Parts of the research area are carrigues, where the most common plants are *Juniperus oxycedrus*, *Paliurus australis*, degraded *Quercus ilex*, *Q. pubescens*, *Carpinus orientalis* and *Rubus* sp.; others are covered by planted forests of *Pinus halepensis*, *P. niger dalmatica* and *P. pinea*. In the northeast of the lake there are also some meadows. The biggest towns and villages (Biograd, Pakoštane, Vrana, Drage, Pirovac) are surrounded and interspersed by partly abandoned vineyards and orchards separated by stone walls.

Thirteen reptilian and two amphibian species were found to occur in Lake Vrana and its vicinity.

Bombina variegata ssp. - One specimen seen in a small pool used for irrigating the fields between Pakoštane and camp Vrana. Subspecific status not determined. First record from Lake Vrana. According to TVRTKOVIĆ & KLETČEKI (1993a) the Velebit mountains are inhabited by *B. v. variegata* (LINNAEUS, 1758). For Mt. Biokovo, which lies south of Lake Vrana, the subspecies is not indicated (TVRTKOVIĆ & KLETČEKI 1993b).

Rana sp. - Numerous in the shallow

Abb. 1: Der Vrana See und seine Umgebung (Dalmatien, Kroatien).

water of Lake Vrana, in canals and pools used for irrigating the fields; also in small streams. 30 specimens in a canal which was 30 m long and 1 m wide; up to 10 specimens per pool. The Green frogs of Dalmatia were generally recognized as *R. ridibunda* PALLAS, 1771 (e. g., NÖLLERT & NÖLLERT 1992) which also inhabits Mt. Velebit (TVRTKOVIĆ & KLETEČKI 1993a). Based on bioacoustic evidence (SCHNEIDER & SINSCH 1992; SCHNEIDER & HAXHIU 1994), *R. balcanica* SCHNEIDER & SINSCH, 1992 was described from south of the Plitvica Lakes. Thus, without detailed bioacoustic and enzyme electrophoretic analyses, the systematic status of the Green Frogs of Lake Vrana remains unclear.

Testudo hermanni boettgeri (MOJSIĆOVICS, 1889) - Numerous in different habitats, especially in carrigues. Frequently found in numbers of 5 to 6 specimens. All captured and measured tortoises were immature females according to the criteria in CARRETERO & al. (1995).

Emys orbicularis (LINNAEUS, 1758) - Common in Lake Vrana and in the neighbouring canals. Juveniles in small pools which are no longer used for irrigating the fields and, thus, are covered by floating vegetation. I found four juveniles in a pool of 9 m² in size. *Emys* was never found in pools that were bare of water vegetation.

Ophisaurus apodus (PALLAS, 1775) - One specimen (approximately 1 m; dead) on the road from Pakoštane to Vrana.

Lacerta trilineata major (BOULENGER, 1887) - Present in various habitats (e. g., clearings, pastures, coastal rocks). The highest density (13.4 specimens/ha) determined by the transect method was found

on a rocky clearing in a *Pinus halepensis* plantation. In coastal areas in Bulgaria, the density of *L. trilineata* was between 22.5 and 25 specimens/ha (NETTMANN & RYKENA 1984).

Lacerta oxycephala DUMÉRIL & BIBRON, 1839 - One specimen on a stone wall near the road in Drage village. The northern limit of the species' range was thought to be the river Krka and the area of the town Sibenik, while records from Zadar might not be reliable (RADOVANOVIC 1951; BISCHOFF 1984). The new record from Drage is about 30 km north of the hitherto northernmost locality records of this species.

Podarcis sicula campestris (DE BETTA, 1857) - Most common reptile species in the area, abundant in Pakoštane. For morphometric characters see table 1.

Coluber najadum dahlii SCHINZ, 1833 - One specimen in the camp near Pakoštane, few meters from the sea. This species is rare also on Mt. Velebit (MRSIĆ 1977).

Coluber gemonensis (LAURENTI, 1768) - This snake was found in 40% of the habitats under study (carrigues, clearings, pastures with stone walls). Its density estimated from the transect method was 2.8 specimens/ha in a rocky clearing of a *Pinus* sp. forest. For morphometric characters see table 2.

Elaphe quatuorlineata quatuorlineata (LACÉPÈDE, 1798) - One specimen (dead) on the main road between Pakoštane and Drage.

Elaphe longissima longissima (LAURENTI, 1768) - One adult specimen (dead) on the road between Radovanovic i and Banevci. On both sides of the road is car-

main road between Pakoštane and Vrana, very close to Lake Vrana; one juvenile in the lake.

Telescopus fallax fallax (FLEISCHMANN, 1837) - One adult specimen (dead) on the road between Pakoštane and Vrana.

ACKNOWLEDGMENTS

I am grateful to MILAN VOGRIN for assistance with field work and his comments to the manuscript.

Special thanks to POLONA ŽAGAR for the linguistic improvement of the manuscript.
