Abstract. In this paper we present the identification of an introduced population of *Podarcis muralis*, located outside of its distribution area in Romania, in the Crișul Repede (Sebes-Körös) Plain, in north-western Romania. In total, based on the individual colour, we identified 58 common wall lizard adults. We also captured 23 juveniles. The area occupied by the individuals of *Podarcis muralis* was estimated to be approximately 950 square meters. The identified common wall lizard population can be considered as a self-sustaining population rather than a sink population, with probability of dispersion.

Key words: native species, alien species, syntopic, distribution range, protected area, Natura 2000 network.

Podarcis muralis is a sub-Mediterranean species, native to Europe, with wide distribution (Gasc 1997, Böhme et al. 2009). The species is at the northern limit of its range in Romania, occurring primarily along the Carpathian Mountains and in several sites in the Danube River Basin and Dobruja (for distribution review, see Cogălniceanu et al. 2013). The abundance of the species in certain Romanian areas is also an indicator of the sub-Mediterranean influences which are felt in these regions (Covaciuc-Marcov et al. 2009).

However, the common wall lizard is also important as species with high colonization power, being recorded many cases of the introduction of *Podarcis muralis* in territories outside the distribution area (see Table A1 in Kraus 2009). Thus the species has been introduced in different places of Europe, of which many extended the northern limit of its range (e.g. Germany – Schulte et al. 2011; Czech Republic – Šandera 2013; Poland – Wirga & Majtyka 2013; and for varying periods of time in southern England – for review, see Beebee & Griffiths 2000).

At the same time, there are also documented cases on the establishment of species in the New World, both in the United States (Hedeen 1984, cited in Deichsel & Gist 2001) and Canada (Gregory & Gregory 1999, Deichsel & Schweiger 2004, and the other references cited in Allan et al. 2006).

Both native and introduced populations have a high potential for natural expansion along railroad tracks. This has been observed in the invasive populations from USA (Hedeen & Hedeen 1999)

and in populations from the natural range (e.g. Kühnis & Schmocker 2008 cited in Schulte et al. 2013) as well, including Romania (Covaciuc-Marcov et al. 2006, Strugariu et al. 2008, Gherghel et al. 2009).

In this paper we present the identification of a probably introduced population of *Podarcis muralis*, located outside of its distribution area in Romania, in the Crișul Repede (Sebes-Körös) Plain, in north-western Romania.

On 24th March 2012, guided by the custodian of the Natura 2000 site "Lunca Inferioară a Crișului Repede" (ROSCI0104), next to the dam near Tărian locality ($47^{\circ}5'17.80"N, 21^{\circ}47'2.11"E$) (Fig. 1) we observed and captured three individuals (two males and one female) of *Podarcis muralis*. Afterwards, in 2013 we revisited the habitat in March, May and September in order to confirm the presence of the identified population and to gather additional data about it. During the fieldworks in 2013 we have expanded the research area. Common wall lizards were captured by hand or were photographed in situ with Tamron SP 90mm f/2.8 Di Macro 1:1 lens mounted on a Canon EOS-600D digital camera. Snout-vent length (SVL) of captured individuals was measured using a digital dial calliper with 0.01 mm accuracy.

In total, based on the individual colour, we identified 58 common wall lizard adults (Fig. 2). In September 2013 we captured 23 juveniles. SVL of the smallest adult was 49mm, and of the largest adult 81mm (232mm with tail). The smallest juvenile was only 21mm SVL (Fig. 3). The area occupied by the individuals of *Podarcis muralis* was estimated to be approximately 950 square meters.

Figure 2. Adult individuals of *P. muralis* from the studied area.

Figure 3. Juvenile of *P. muralis* from the studied area.

The identified population is about 40 and 46 km away from the nearest known population of *Podarcis muralis* in the Apuseni Mountains (at Vârciorog and Peștiș localities – Covaciuc-Marcov et al. 2003).

The first three individuals of *Podarcis muralis* (in 2012) were sampled from the gabions brought several years ago to fortify the right bank of the river Crișul Repede (Sebes-Körös) downstream of the dam from Tărian. Based on the observation

made, we concluded that the individuals have arrived recently, with the gabions meant to strengthen the bank of river. Such introductions with building materials are certainly common, but often insufficient to form a population with long-term viability.

Therefore, we intended to revisit the place next year to see if there are common wall lizards anymore and if there is a possibility of their establishment in the future. During fieldworks in 2013 we have noticed that the gabions are not the only habitat used by the individuals of *Podarcis muralis* (Fig. 4). We have found a high number of adults (27) including on the stones and pieces of concrete left since the building of the dam at Tărian. Therefore, the species' presence must be much older, dating probably from the 70s when intense hydro-technical works had been performed along the Crișul Repede River (Petrea et al. 2006). This is the only feasible explanation of the presence of species in the studied habitat, since there is no railway communication nearby. The nearest population that inhabits railroads is at a distance of 54 km, where the species arrived from Apuseni Mountains due to the habitat provided by railways (Covaciuc-Marcov et al. 2006).

The considerations on the age of the identified population of *Podarcis muralis* are not in contradiction with the available herpetofaunistic data (Covaciuc-Marcov et al. 2000), considering both the location of the population and the small area occupied, which did not allow an easy recording; even its current discovery was owed to chance.

The hypothesis of the longer presence of the *Podarcis muralis* population is also strengthened by the fact that larger individuals (SVL greater than 70mm) occurred near the dam, while averaged sized individuals (SVL=49-63mm) used mostly the gabions. Juveniles occurred mainly in the dry vegetation on the concrete alley that connects the dam and the gabions. It is well known that the wall lizards have a pronounced territoriality, adult males defending their home ranges (Boag 1973 cited in Schulte et al. 2013). Due to this spatial structuring, the young individuals may become floating ones, dispersers of the population (Boag 1973). But in the case of non-native individuals / populations it can be observed a decrease of territoriality, probably due to the pressure of the environment (e.g. in the case of US populations - Brown et al. 1995). If non-native populations have suitable area with many unoccupied habitats, and suitable pathways of dispersion, the younger

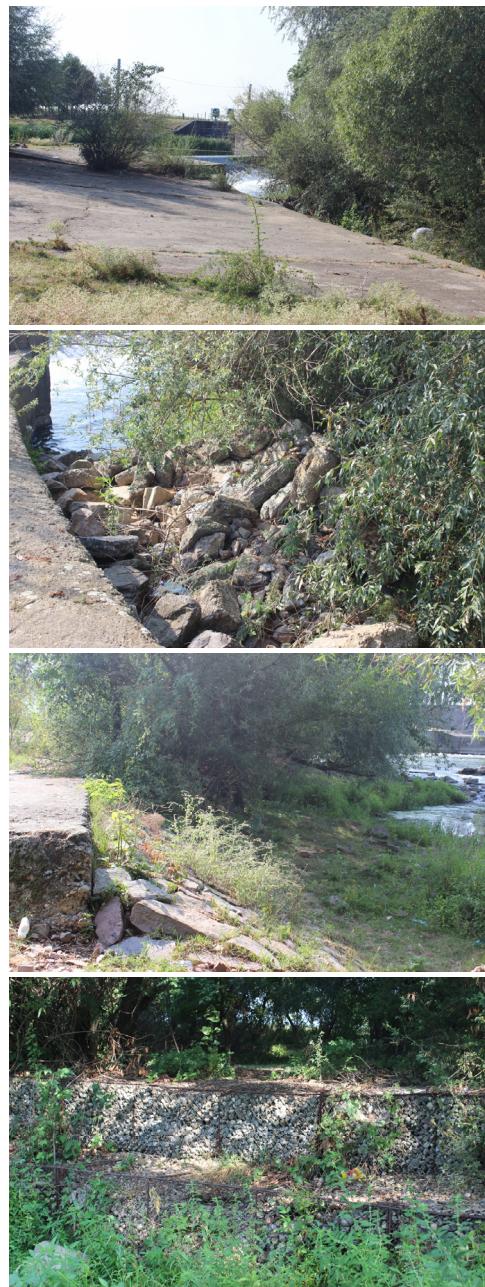

Figure 4. Basking sites of *P. muralis* in the studied area.

(floating) individuals may become dispersers rather than competitors (Schulte et al. 2013). Before the bringing of gabions the individuals of the population probably had to cope with a limited availability of basking sites, near the dam. The fact that we did not identify males that suffered tail

loss, also indicates a more reduced territoriality of males, at least in the past. With the start of the arrangement of the river bank and the setup of gabions, the suitable habitat increased immediately, and this could lead to the retrieval of territoriality.

The only species of lizard occurring syntopically in the surveyed habitat is *Lacerta agilis*. In the speciality literature *Podarcis muralis* is considered an aggressive species (Gruschwitz & Böhme 1986, cited in Deichsel & Gist 2001), with pronounced territoriality (Edsman 1990, cited in Heym et al. 2013) and high invasiveness potential (e.g. Behler & King 2000), to which syntopic species always exhibit an avoidance response (e.g. Bertram 2004, cited in Heym et al. 2013, Schulte et al. 2012). Concerning the investigated population we did not observe such avoidance behaviour of the syntopic *Lacerta agilis* individuals. Most likely the lack of aggressive behaviour against *Lacerta agilis* is primarily due to the use of different basking substrate. In the surveyed habitat, *Podarcis muralis* uses as basking site the rocks from the dam and the gabions, while *Lacerta agilis* uses the sites covered with vegetation, which are often shadier. This observation is consistent with the results of Heym et al. (2013).

Nevertheless, a hypothetical problem might occur if the project of hydrotechnical improvement of Crișul Repede (Sebes-Körös) River (announced in 2012) downstream of the municipality of Oradea to the border with Hungary (announced in local press, i.e. Țic 2012) is realised. This project implies bank armouring as well, most likely with gabions, which could favour the expansion of the *Podarcis muralis* population along the lowland section of Crișul Repede (Sebes-Körös) River. After Allan et al. (2006) these lizards clearly have reached high numbers fairly quickly from very small founding populations. Presently, the population is limited by the size of suitable area. Enlarging the interaction area between the introduced common wall lizard and the sand lizard, across the entire lowland section of Crișul Repede (Sebes-Körös) River could raise conservation issues. Both species are native in Romania, and also species of community interest in need of strict protection through the Habitats Directive (Council Directive 92/43/EEC) and its Romanian national projection (O.U.G. 57/20.06.2007).

In conclusion the identified *Podarcis muralis* population can be considered as a self-sustaining population rather than a sink population, with probability of dispersion. But a long term monitor-

ing is needed to evaluate the future implications of the population on the biodiversity of the area.

Acknowledgement. First at all, we want to thank Aqua Crisiș Asociație, Oradea, Romania <<http://www.aquacrisius.ro>>, the custodian of the protected area, for the access permission. We also want to thank the persons who accompanied us during field study in 2012 (Mihai Togor - leader of Aqua Crisiș; Diana Cupșa and Ilie Telcean - University of Oradea), and in 2013 (Adina Pop, Florin Pantiș - candidates for BSc in Biology at the University of Oradea).
